

# Numerical Methods for Partial Differential Equations - Notes - v0.3.0

260236

September 2025

## Preface

Every theory section in these notes has been taken from the sources:

- Course slides. [\[1\]](#)

About:

 [GitHub repository](#)

These notes are an unofficial resource and shouldn't replace the course material or any other book on numerical methods for partial differential equations. It is not made for commercial purposes. I've made the following notes to help me improve my knowledge and maybe it can be helpful for everyone.

As I have highlighted, a student should choose the teacher's material or a book on the topic. These notes can only be a helpful material.

## 1 Basic Concepts

In this course, we introduce numerical methods for the solution of **Partial Differential Equations** (PDEs), with focus on the **Finite Element** (FE) **method**<sup>1</sup> and the use of the computer for the construction of the PDEs numerical solution.

We will consider the numerical approximation of elliptic and parabolic PDEs by considering their variational formulation, Galérkin and FE approximations in 1D/2D/3D, the theoretical properties and practical use of the methods, algorithmic aspects, and interpretation of the numerical results.

Advanced topics include the approximation of saddle-point PDEs (Stokes equations), vectorial, nonlinear, and multiphysics differential problems, domain decomposition methods exploiting the properties of the PDEs, and the introduction to parallel computing for the FE method, i.e., in the *High Performance Computing* (HPC) framework.

Finally, the course will feature the use of the [deal.II software library](#), a C++ open source FE library, and [ParaView](#) for the visualization of numerical solution and scientific computing data.

---

<sup>1</sup>The **Finite Element Method (FEM)** is a popular method for numerically solving differential equations arising in engineering and mathematical modeling. Typical problem areas of interest include the traditional fields of structural analysis, heat transfer, fluid flow, mass transport, and electromagnetic potential. Computers are usually used to perform the calculations required. With high-speed supercomputers, better solutions can be achieved, and are often required to solve the largest and most complex problems. ([source](#))

## 1.1 Mathematical Models and Scientific Computing

### Definition 1: Mathematical Model

A **Mathematical Model** is a set of (algebraic or differential) equations that is able to represent the features of a complex system or process.

#### ? Why do they exist?

Models are **developed** to:

- Describe
- Forecast
- Control

The **behavior or evolution of such systems**.

We are interested in the physics models. **Physics-based models** are those **mathematical models that are derived from physical principles** (like conservation laws of mass, momentum, energy, etc.) **and that encode natural laws of leading to (differential) equations whose solutions are often represented in the form of functions**. However, the analytical solution of such models is rarely available in closed form, for which numerical approximation methods are instead employed.

### Definition 2: Numerical Modelling

**Numerical Modelling** indicates sets of numerical methods that **determine an approximate solution of the original** (often infinite-dimensional) **mathematical model**, by turing it into a *discrete problem* (algebraic, finite-dimensional), whose dimension (size) is typically very large.

### Definition 3: Scientific Computing

**Scientific Computing** is a branch of Mathematics that **numerically solves (differential) mathematical models by building approximate solutions though the use of a calculator**.

For numerical models of large size, parallel architectures for calculators and the HPC framework are typically used.

### ❓ Why did we introduce mathematical models and physical models?

Because they are connected and used together. Mathematical models are conventionally used altogether with theoretical (mathematical) models and experimental tests. Unfortunately, in several cases theoretical models are not available (like in Computational Medicine) or experimental tests are not meaningful or cannot be performed (for example, for nuclear testing). Physics-based models have witnessed an increasing role in the modern society in virtue of the massive developments of Scientific Computing and computational tools.

Since a large amount of data is becoming available from multiple sources nowadays, data-driven models are fundamentals. **Data-driven models** are those mathematical models built from meaningful data that do not rely on physical principles, because the latter are not available or are not reliable, and whose construction calls for statistical learning methods.

Physics-based mathematical models (**mathematical problems**) are a fundamental pillar in the understanding and prediction of several physical phenomena and processes (**physical problems**). However, these mathematical models lead to problems that can rarely be solved analytically, or in an exact way (**exact solution**), especially for PDEs: with only a few exceptions, it is not possible to write their solution explicitly.

Numerical methods and numerical approximation techniques (**numerical problems**) serve the purpose to determine an **approximate solution** of a mathematical model. When the calculator is used to determine such approximate solution, the latter is called **numerical solution** (see the Figure 1).

Figure 1: Scientific Computing.

## 1.2 Differential Models and PDEs

### Definition 4: Partial Differential Equation (PDE)

A **differential equation** (model) is an equation that involves **one or more derivatives of an unknown function**. In an **Ordinary Differential Equation (ODE)**, every derivative of the unknown solution is with respect to a single independent variable. If instead, derivatives are partial, then we have a **Partial Differential Equation (PDE)**.

In other words, it is a differential equation where its derivatives are partial.

There are different types of PDEs, and their nature depends on the conditions and their type. Mathematically, we can represent a **differential model** (equation) as follows:

$$\mathcal{P}(u; g) = 0 \quad \text{differential equation (mathematical problem)} \quad (1)$$

Where:

- $\mathcal{P}$  indicates the *model*;
- $u$  is the *exact solution*, a function of one or more independent variables (space and/or time variables);
- $g$  indicates the *data*.

### 1.2.1 ODEs

**Ordinary Differential Equation (ODE)** is also known as **initial value problem**.

#### ☐ I°ODE - Cauchy problem

A **first order ODE**, a **Cauchy problem**, is a differential problem, whose:

- **Solution**  $u = u(t)$  is a function of a single independent variable  $t$ , often interpreted as time.
- A **single condition** is assigned on the solution, at a point (usually, the left end of the integration interval).

Its form is the following find  $u : I \subset \mathbb{R} \rightarrow \mathbb{R}$  such that:

$$\begin{cases} \frac{du}{dt}(t) = f(t, u(t)) & t \in I \\ u(t_0) = u_0 \end{cases} \quad (2)$$

Where:

- $I = (t_0, t_f] \subset \mathbb{R}$  is a **time interval**;
- $u_0$  is the **initial value** assigned at  $t = t_0$ ;
- $f : I \times \mathbb{R} \rightarrow \mathbb{R}$

🔍 **Meaning.** The equation describes the **evolution of a scalar quantity**  $u$  over time  $t$ , **without distribution in space**.

🔍 **Vectorial problems.** In vectorial problems, the **unknown is a vector-valued function**  $\mathbf{u} = \mathbf{u}(t)$ , where  $\mathbf{u} = (u_1, \dots, u_m) \in \mathbb{R}^m$ , with  $m \geq 1$ . The first order Cauchy problem reads: find  $\mathbf{u} : I \subset \mathbb{R} \rightarrow \mathbb{R}^m$  such that:

$$\begin{cases} \frac{d\mathbf{u}}{dt}(t) = \mathbf{f}(t, \mathbf{u}(t)) & t \in I \\ \mathbf{u}(t_0) = \mathbf{u}_0 \end{cases}$$

Where  $\mathbf{u}_0 \in \mathbb{R}^m$  is the initial datum and  $\mathbf{f} : I \times \mathbb{R}^m \rightarrow \mathbb{R}^m$ .

#### ☐ II°ODE - Cauchy problem

A **second order Cauchy problem** sees second order time derivatives and two initial conditions. It reads as: find  $u : I \subset \mathbb{R} \rightarrow \mathbb{R}$  such that:

$$\begin{cases} \frac{d^2u}{dt^2}(t) = f\left(t, u(t), \frac{du}{dt}(t)\right) & t \in I \\ \frac{du}{dt}(t_0) = v_0 \\ u(t_0) = u_0 \end{cases} \quad (3)$$

Where the initial data are  $u_0$  and  $v_0$ , while  $f : I \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ .

### 1.2.2 PDE, boundary value problem in 1D

The **Boundary value problem in 1D** is characterized by a **single independent variable**  $x$ , which represents the **space coordinate in an interval**  $\Omega = (a, b) \in \mathbb{R}$  (1D).

The problem involves **second order derivatives of the unknown solution**  $u = u(x)$  with respect to  $x$ . The value of  $u$ , or the **value of its first derivate**, is a **set at the two boundaries of the domain** (interval)  $\Omega$ , that is at  $x = a$  and  $x = b$  (the domain boundary is  $\partial\Omega = \{a, b\}$ ).

Let us consider the following **Poisson problem** with (homogeneous) Dirichlet boundary conditions: find  $u : \Omega \subset \mathbb{R} \rightarrow \mathbb{R}$  such that:

$$\begin{cases} -\frac{d^2u}{dx^2}(x) = f(x) & x \in \Omega = (a, b) \\ u(a) = u(b) = 0 \end{cases} \quad (4)$$

This equation models a **stationary phenomenon** (the time variable doesn't appear in fact) and represent a **diffusion model**.

#### Example 1

For example, the diffusion model models the diffusion of a pollutant along a 1D channel  $\Omega = (a, b)$  or the vertical displacement of an *elastic thread* fixed at its ends. In the first case,  $f = f(x)$  indicates the source of the pollutant along the flow, while in the second case,  $f$  is the traverse force acting on the elastic thread, in the hypothesis of negligible mass and small displacements of the thread.

### Boundary value problem in 1D vs ODE

We remark that the **boundary value problem in 1D is a particular case of PDEs**, even if it involves only derivatives with respect to a single independent variable  $x$ . Indeed, even if apparently similar to a second order ODE, the boundary value problem is in reality substantially **different** from an ODE:

- In ODE, two conditions are set at  $t = t_0$ ;
- In the boundary value problem in 1D, one condition is set at  $x = a$  and the other one at  $x = b$ .

The conditions in the boundary value problem determine to the so-called global nature of the model.

### 1.2.3 PDE, initial and boundary value problem in 1D

**Initial and boundary value problem in 1D** is a type of problems that concern equations that **depend on space and time**:

- The **unknown solution**  $u = u(x, t)$  both depends on the space coordinate  $x \in \Omega \subset \mathbb{R}$  in 1D;
- The **time variable**  $t \in I \subset \mathbb{R}$ .

In this case, the initial conditions at  $t = 0$  must be prescribed, as well as the boundary conditions at the ends of the interval in 1D.

The **Heat equation**, also known as **Diffusion equation**, with Dirichlet boundary conditions assumes the following form: find  $u : \Omega \times I \rightarrow \mathbb{R}$  such that:

$$\begin{cases} \frac{\partial u}{\partial t}(x, t) - \mu \frac{\partial^2 u}{\partial x^2}(x, t) = f(x, t) & x \in \Omega = (a, b), t \in I \\ u(a, t) = u(b, t) = 0 & t \in I \\ u(x, t_0) = u_0(x) & x \in \Omega = (a, b) \end{cases} \quad (5)$$

#### Example 2

For example, the unknown function  $u(x, t)$  describes the temperature in a point  $x \in \Omega = (a, b)$  and time  $t \in I$  of a metallic bar covering the space interval  $\Omega$ . The diffusion coefficient  $\mu$  represents the thermal response of the material and it is related to its thermal conductivity. The Dirichlet boundary conditions express the fact that the ends of the bar are kept at a reference temperature (zero degrees in this case), while at time  $t = t_0$  the temperature is assigned in each point  $x \in \Omega$  through the initial function  $u_0(x)$ . Finally, the bar is subject to a heat source of linear density  $f(x, t)$ .

### 1.2.4 PDE, boundary value problem in multidimensional domains

The Poisson problem (equation 4, page 9) can be **extended in multidimensional domains**  $\Omega \subset \mathbb{R}^d$ , with  $d = 2, 3$ ; the solution is  $u = u(\mathbf{x})$ , where  $\mathbf{x} = (x_1, \dots, x_d)^T \in \mathbb{R}^d$ . This leads to the following Poisson problem with (homogeneous) Dirichlet boundary conditions: find  $u : \Omega \subset \mathbb{R}^d \rightarrow \mathbb{R}$  such that:

$$\begin{cases} -\Delta u = f & \text{in } \Omega \text{ (i.e. } \mathbf{x} \in \Omega) \\ u = 0 & \text{on } \partial\Omega \text{ (i.e. } \mathbf{x} \in \partial\Omega) \end{cases} \quad (6)$$

Where:

- The **Laplace operator**:

$$\Delta u(\mathbf{x}) := \sum_{i=1}^d \frac{\partial^2 u}{\partial x_i^2}(\mathbf{x})$$

- The **domain**  $\Omega \subset \mathbb{R}^d$  is endowed with boundary  $\partial\Omega$ ;
- $f = f(x)$  is the **external forcing term**.

This equation is used **for example** to **model the vertical displacement of an elastic membrane fixed at the boundaries**.

### 1.2.5 PDE, initial and boundary value problem in multidimensional domains

The **multidimensional** counterpart of the **heat equation** (5, page 10) reads: find  $u : \Omega \times I \rightarrow \mathbb{R}$  such that:

$$\begin{cases} \frac{\partial u}{\partial t} - \mu \Delta u = f & \mathbf{x} \in \Omega, t \in I \\ u(\mathbf{x}, t) = 0 & \mathbf{x} \in \partial\Omega, t \in I \\ u(\mathbf{x}, t_0) = u_0(\mathbf{x}) & \mathbf{x} \in \Omega \end{cases} \quad (7)$$

Where  $u_0$  is the **initial datum**. The **solution** is  $u = u(\mathbf{x}, t)$ .

### 1.2.6 Classification of PDEs

A PDE is a relationship among:

- The partial derivatives of a function  $u = u(\mathbf{u}, t)$ , that is the PDE **solution**;
- **Spatial coordinates**  $\mathbf{x} = (x_1, \dots, x_d)^T \in \mathbb{R}^d$  on which the solution depends (if the problem is defined in a spatial domain  $\Omega \subset \mathbb{R}^d$ ).
- **Time variable**  $t$ .

Therefore, a PDE can be written as:

$$\mathcal{P}\left(u, \frac{\partial u}{\partial t}, \frac{\partial u}{\partial x_1}, \dots, \frac{\partial u}{\partial x_d}, \dots, \frac{\partial^{p_1+\dots+p_d+p_t} u}{\partial x_1^{p_1} \dots \partial x_d^{p_d} \partial t^{p_t}}, \mathbf{x}, t; g\right) = 0 \quad (8)$$

Where  $p_1, \dots, p_d, p_t \in \mathbb{N}$  and  $g$  are the data.

#### Definition 5: PDE order

The **PDE order** is the **maximum order of derivation** that appears in  $\mathcal{P}$ , that is:

$$q = p_1 + \dots + p_d + p_t \quad (9)$$

#### Definition 6: PDE is linear

The **PDE is linear** if  $\mathcal{P}$  **linearly depends** on  $u$  and its **derivatives**.

### √ Classification

Let us focus on linear PDEs of order  $q = 2$  with constant coefficients, so that the general PDE formulation is:

$$\mathcal{L}u = g$$

Where  $\mathcal{L}$  is a second order, **linear differential operator**. When only two independent variables (our case)  $x_1$  and  $x_2$  are considered, the operator  $\mathcal{L}$  applied to the function  $u$  reads:

$$\mathcal{L}u = A \cdot \frac{\partial^2 u}{\partial x_1^2} + B \cdot \frac{\partial^2 u}{\partial x_1 \partial x_2} + C \cdot \frac{\partial^2 u}{\partial x_2^2} + D \cdot \frac{\partial u}{\partial x_1} + E \cdot \frac{\partial u}{\partial x_2} + F \cdot u$$

For some constant coefficients  $A, B, C, D, E, F, G \in \mathbb{R}$ . If  $d = 2$  (our case), the **independent variables** can represent the *space coordinates*:

- $x_1 = x$
- $x_2 = y$

After introducing the **PDE discriminant** (a quantity that helps determine the type of PDE):

$$\Delta := B^2 - 4AC \quad (10)$$

The PDE can be classified as:

- **Elliptic PDE** if  $\Delta < 0$
- **Parabolic PDE** if  $\Delta = 0$
- **Hyperbolic PDE** if  $\Delta > 0$

**🔍 What are the implications of PDE classification?**

The different nature of the PDE impacts on:

- **Type and amount of data to prescribe as boundary;**
- **Initial conditions** to ensure the well-posedness of the problem (existence and uniqueness of the solution);
- The **phenomena that can be described** by the PDE;
- The **information that encapsulates**.

In general:

- **Elliptic PDE** typically describes **stationary phenomena**, without time evolution of quantities.
- **Parabolic PDE** describes **wave propagation phenomena** with infinite velocity of propagation.
- **Hyperbolic PDE** describes **wave propagation phenomena** but with finite velocity of propagation.

### 1.3 Numerical Methods

Since in most cases of practical interest we **cannot solve a PDE analytically**, we need to use **numerical methods** that allow us to construct an *approximation*  $u_h$  of the *exact solution*  $u$ , for which the corresponding *error*  $(u - u_h)$  can be quantified and/or estimated.

$$\begin{array}{ccc}
 \mathcal{P}(u; g) = 0 & & \text{PDE (mathematical problem)} \\
 \downarrow & & \text{numerical method} \\
 \mathcal{P}_h(u_h; g_h) = 0 & & \text{approximate PDE (numerical problem)}
 \end{array}$$

Where:

- $g_h$  is an approximation of the data  $g$ ;
- $\mathcal{P}_h$  is a characterization of the approximate problem.

The subscript  $h$  indicates a **discretization parameter** that characterizes the numerical approximation. Conventionally, the smaller is  $h$ , the better is the approximation of  $u$  made by  $u_h$ . Furthermore, the error  $(u - u_h)$  tends to zero as  $h$  gets smaller and smaller. In this course, we will specifically introduce the FE method (page 4) to build the numerical approximation of PDEs.

#### ■ Summary Notation

Notation	Description
$\mathcal{P}(u; g) = 0$	PDE (mathematical problem)
$u$	<i>exact solution</i> of a PDE
$u_h$	<i>approximate solution</i> of a PDE
$(u - u_h)$	<i>error</i> (quantified and/or estimated; tends to zero if $h$ is smaller)
$h$	<i>discretization parameter</i> ( $\downarrow$ smaller $h$ , better approximation; $\uparrow$ higher $h$ , poor approximation)
$\mathcal{P}_h(u_h; g_h) = 0$	approximate PDE (numerical problem)
$g_h$	<i>approximation</i> of the <i>data</i> $g$
$\mathcal{P}_h$	<i>characterization</i> of the approximate problem.

Table 1: Notation used to approximate the PDE with numerical methods.

## 1.4 From Mathematical to Numerical Problem

### 1.4.1 The Mathematical Problem (MP)

Let us consider a **Physical Problem (PP)** endowed with a **physical solution**, let say  $u_{ph}$ , and **dependent on data** indicated with  $g$ .

The **Mathematical Problem (MP)** is represented by the **mathematical formulation of the PP** and has **mathematical solution**  $u$ . Therefore, we indicate the MP as:

$$\mathcal{P}(u; g) = 0 \quad (11)$$

Where:

- $u \in \mathcal{U}$
- $g \in \mathcal{G}$ , and  $\mathcal{G}$  is the set or space of **admissible data**.

Where  $\mathcal{U}$  and  $\mathcal{G}$  are suitable sets or spaces.

#### Definition 7: Model Error

The error between the physical and mathematical solutions is called **Model Error**:

$$e_m := u_{ph} - u \quad (12)$$

Where:

- $u_{ph}$  is the physical solution;
- $u$  is the mathematical solution.

The model error takes into account all those **characteristics of the PP that are not represented or captured by the MP**.

### ? When a Mathematical Problem is *well-posed*?

#### Definition 8: *well-posed* MP

The mathematical problem MP is *well-posed* (**stable**) if and only if there **exists a unique solution**  $u \in \mathcal{U}$  **that continuously depend on the data**  $g \in \mathcal{G}$ .

From the previous definition, we remark that  $\mathcal{G}$  is the set of admissible data, i.e., those for which the MP admits a unique solution. Furthermore, *continuously depend on the data* means that **small perturbations on data**  $g \in \mathcal{G}$  **lead to small changes on the solution**  $u \in \mathcal{U}$  of the MP. However, a measure of this sensitivity is given by the condition number of the MP.

### 1.4.2 The Numerical Problem (NP)

The **Numerical Problem (NP)** is an **approximation of the Mathematical Problem** (MP, equation 11, page 15). We indicate its **numerical solution** as  $u_h$ , where  $h$  stands as a suitable **discretization parameter**.

$$\mathcal{P}_h(u_h; g_h) = 0 \quad (13)$$

Where:

- $u_h \in \mathcal{U}_h$
- $g_h \in \mathcal{G}_h$ , and  $g_h$  is the representation of the **data in the NP**.

Where  $\mathcal{U}_h$  and  $\mathcal{G}_h$  are suitable sets or spaces.

#### Definition 9: Truncation Error

The error between the mathematical and numerical solutions is called **Truncation Error**:

$$e_h := u - u_h \quad (14)$$

Where:

- $u$  is the mathematical solution;
- $u_h$  is the numerical solution.

The truncation error can be considered as the error resulting from the **discretization of the MP**.

#### Numerical solution calculated on the computer

When the numerical solution is computed by running the algorithm on a computer, we need more notations and concepts.

- $\hat{u}_h$  is the **final solution**.
- The final solution is affected by a **Round-Off error**  $e_r$ :

$$e_r := u_h - \hat{u}_h \quad (15)$$

Such round-off errors depend on the machine architecture, on the representation of the numbers at the calculator, and on operations made in floating-point arithmetic.

- The truncation error  $e_h$  (equation 14, page 16) and the Round-Off error  $e_r$  (equation 15) concur to determine the **Computational error**  $e_c$ :

$$e_c := e_h + e_r = (u - u_h) + (u_h - \hat{u}_h) = u - \hat{u}_h \quad (16)$$

For some NP, we can have a round-off error less than a truncation error  $|e_r| \ll |e_h|$ , for which  $e_c \approx e_h$ .

### ? When a Numerical Problem is *well-posed*?

#### Definition 10: *well-posed* NP

The numerical problem NP is *well-posed* (**stable**) if and only if there **exists a unique solution**  $u_h \in \mathcal{U}_h$  **that continuously depends on the data**  $g_h \in \mathcal{G}_h$ .

### Consider the numerical solution calculated only on the computer

In practice, numerical solutions are computed on a computer. Therefore, it is reasonable to obtain a computational error that tends to zero as the numerical method improves, namely as the discretization parameter  $h$  goes to zero. This concept is encoded in the definition of convergence.

#### Definition 11: *convergence* NP

The NP is **convergent** when the **computational error tends to zero** for  $h$  tending to zero, that is:

$$\lim_{h \rightarrow 0} e_c = 0 \quad (17)$$

A crucial aspect is to qualify the convergence of the NP, that is determining the convergence order of the NP.

#### Definition 12: *convergence order*

If  $|e_c| \leq Ch^p$ , with  $C$  a positive constant independent of  $h$  and  $p$ , then the NP is **convergent with order**  $p$ .

### ? How to estimate the convergence order?

The convergence order can be estimated for many reasons (error estimation, method comparison, accuracy verification, etc.). If there exists a constant  $\tilde{C} \leq C$  independent of  $h$  and  $p$  such that  $\tilde{C}h^p \leq |e_c| \leq Ch^p$ , then we can write  $|e_c| \approx Ch^p$  and we can **estimate the convergence order  $p$  of the NP by using the known solution  $u$  of the MP**. There are two approaches:

#### 1. Algebraic estimation of $p$ .

- (a) We compute the computational errors  $e_{c1}$  and  $e_{c2}$  for the NP corresponding to two different values of  $h$  that are “sufficiently” small, say  $h_1$  and  $h_2$ .
- (b) Then:
  - Writing  $|e_{c1}| \approx Ch_1^p$  and  $|e_{c2}| \approx Ch_2^p$
  - Noticing that  $\frac{|e_{c1}|}{|e_{c2}|} = \left(\frac{h_1}{h_2}\right)^p$

We estimate the order  $p$  as:

$$p = \frac{\log\left(\frac{|e_{c1}|}{|e_{c2}|}\right)}{\log\left(\frac{h_1}{h_2}\right)} \quad (18)$$

2. **Graphical estimation of  $p$ .** We represent the errors  $|e_c|$  and  $h$  on a plot in log-log scale. As  $\log |e_c| = \log(Ch^p) = \log(C) + p \log(h)$ , we have  $p = \arctan(\theta)$ , where  $\theta$  is the slope of the curve  $(h, e_c)$ , a straight line in log-log scale. Instead of computing  $\theta$ , it is possible to verify that the curves  $(h, e_c)$  and  $(h, h^p)$  are parallel in log-log scale.

In other words it involves plotting the error against the step size on a log-log scale and analyzing the resulting graph:

- (a) **Compute Errors:** Perform the numerical method for several step sizes  $h$ , such as  $h_1, h_2, h_3, \dots$ , and compute the corresponding errors  $e_1, e_2, e_3, \dots$ .
- (b) **Log-Log Plot:** Plot the errors  $e_i$  against the step sizes  $h_i$  on a log-log scale. This means we plot  $\log(h_i)$  on the x-axis and  $\log(e_i)$  on the y-axis.
- (c) **Linear Relationship:** If the method has a convergence order  $p$ , the relationship between the error and the step size should follow  $e \approx Ch^p$ . Taking the logarithm of both sides gives:

$$\log(e) \approx \log(C) + p \log(h)$$

This indicates that the plot of  $\log(e)$  versus  $\log(h)$  should be a straight line with a slope equal to  $p$ .

- (d) **Determine Slope:** The slope of the line in the log-log plot is the convergence order  $p$ . We can estimate this slope by fitting a linear regression line to the data points.

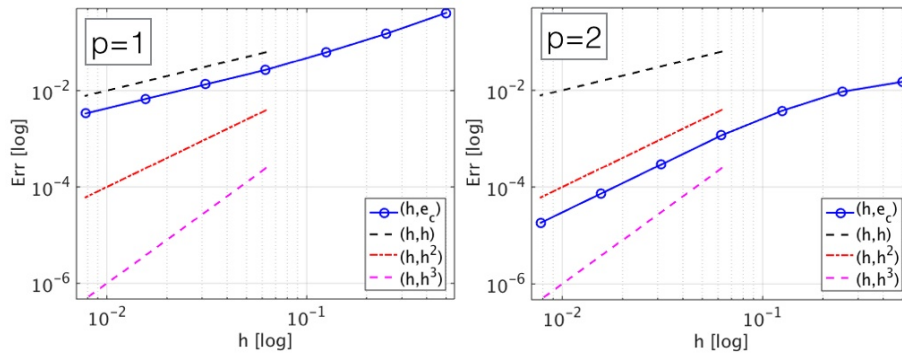

Figure 2: Graphical estimation of the convergence order  $p$  of a NP: computational errors  $|e_c|$  vs  $h$ .

### ❓ When is convergence guaranteed in NP?

Unfortunately, a *well-posed* NP is not necessarily convergent. To ensure convergence of the NP, this is required to satisfy the consistency property (roughly speaking, the NP must be a “faithful copy” of the original MP).

#### Definition 13: NP consisten and strongly consistent

The Numerical Problem NP is **consistent** if and only if:

$$\lim_{h \rightarrow 0} \mathcal{P}_h(u; g) = \mathcal{P}(u; g) = 0 \quad g \in \mathcal{G}_h$$

The Numerical Problem NP is **strongly consistent** if and only if:

$$\mathcal{P}_h(u; g) \equiv \mathcal{P}(u; g) = 0 \quad \forall h > 0, g \in \mathcal{G}_h$$

Let highlights the main differences:

- Definition:
  - **Consistent**. Consistency requires that as the discretization parameter  $h$  tends to zero  $\lim_{h \rightarrow 0}$ , the process  $\mathcal{P}_h(u; g)$  approaches the exact process  $\mathcal{P}(u; g)$  and both become zero. This means that **over time and with finer discretization, the numerical approximation converges to the exact solution**.
  - **Strongly Consistent**. Strong consistency means that for any positive value of  $h$  ( $\forall h > 0$ , no matter how small), the process  $\mathcal{P}_h(u; g)$  is exactly equal to the exact process  $\mathcal{P}(u; g)$  and both are zero. This implies that the **numerical approximation already matches the exact solution for any step size**.
- Condition of  $h$ :
  - **Consistent**. The condition applies in the limit as  $h$  approaches zero. The **process gradually converges to the exact solution as the discretization parameter becomes infinitesimally small**.
  - **Strongly Consistent**. The condition applies for all  $h > 0$ . This is a **stronger requirement** because it demands that the numerical method is **accurate for any discretization parameter**, not just in the limit.

In practice, the *Consistent* indicates that the numerical method improves and approaches the exact solution as the discretization parameter is refined. It guarantees eventual **accuracy, but not necessarily immediate or uniform accuracy for larger  $h$** . On the other hand, *Strongly Consistent* indicates that the numerical method is always accurate, regardless of the discretization parameter. This implies a **higher level of reliability and precision for any  $h$** , making it a stronger and more robust form of consistency.

The **Lax-Richtmyer Equivalence Theorem** is a cornerstone of numerical analysis, linking the concepts of consistency, well-posedness (stability), and convergence. It provides a **rigorous framework for validating numerical methods and ensuring that they produce accurate and reliable solutions**. Furthermore, the following theorem guarantees that if a *numerical problem is well-posed and consistent, then the NP is also convergent*.

**Theorem 1** (Lax-Richtmyer, equivalence). *If the Numerical Problem NP:*

$$\mathcal{P}_h(u_h; g_h) = 0 \quad u_h \in \mathcal{U}_h, g_h \in \mathcal{G}_h$$

*Is consistent:*

$$\lim_{h \rightarrow 0} \mathcal{P}_h(u; g) = \mathcal{P}(u; g) = 0 \quad g \in \mathcal{G}_h$$

*Then, it is well-posed if and only if it is also convergent.*

It is a fundamental theorem in numerical analysis because **it ensures that stability and consistency are sufficient to guarantee convergence**. Conversely, if we have a proof that the NP is consistent, we “only” need to show that the problem is well-posed to automatically prove convergence (and vice versa).

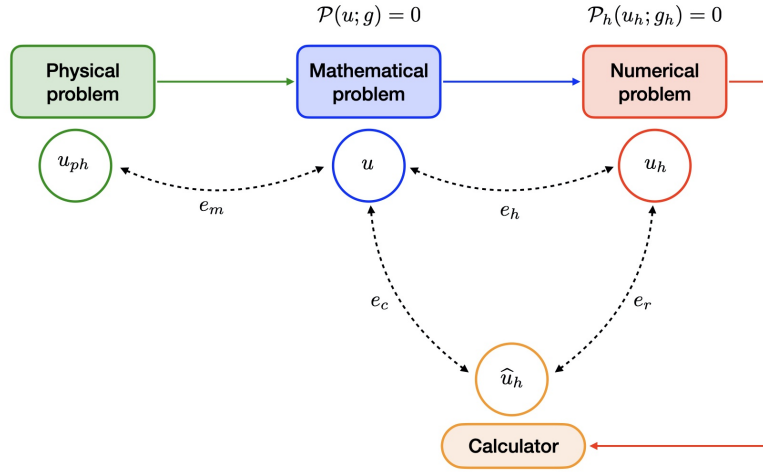

Figure 3: Physical (PP), Mathematical (MP), and Numerical (NP) problems. Corresponding solutions ( $u_{ph}$ ,  $u$ ,  $u_h$ , and  $\hat{u}_h$ ) and errors (model  $e_m = u_{ph} - u$ , truncation  $e_h = u - u_h$ , round-off  $e_r = u_h - \hat{u}_h$ , and computational  $e_c = e_h + e_r$  errors).

## 2 Laboratory

### 2.1 Introduction

The laboratory sessions complement the theoretical course by providing a **hands-on experience** in the numerical approximation of PDEs. The main goal is to bridge the gap between the mathematical formulation of PDEs, their variational and finite element discretizations, and their actual computer implementation.

Throughout the laboratories, we will progressively construct finite element solvers for a variety of model PDEs:

- Starting from the Poisson equation in 1D, moving towards multidimensional diffusion-reaction problems;
- Introducing verification and validation strategies for numerical codes;
- Extending to time-dependent problems such as the heat equation;
- Exploring nonlinear PDEs, elasticity, and saddle-point problems such as Stokes flows.

Each laboratory is designed to emphasize not only the **mathematical correctness** of the discretization, but also the **computational aspects**: efficiency, robustness, and scalability.

### Software

The laboratory relies on:

- `deal.II` is an open-source C++ software library for solving partial differential equations (PDEs) using the finite element method (FEM).

The name `deal.II` stands for “Differential Equations Analysis Library, version II”. It is a finite element framework designed to make it easier to implement complex numerical methods for PDEs. It is widely used in both academia and industry for research, education, and simulation.

**❓ Why is it used in laboratories?** It provides full control over every step of the FEM pipeline: mesh generation, assembly, linear solvers, visualization. It forces us to understand the mathematics and the implementation, instead of just using a black-box solver. Finally, it is well documented and has extensive tutorial programs (step-1, step-2, ...), which the laboratory exercises build upon.

**❓ Why do people say that `deal.II` is complicated?** It’s a C++ library, not a GUI tool. Unlike COMSOL or ANSYS, we write C++ code that uses `deal.II`’s classes. That means we need to understand:

- FEM theory (variational forms, weak formulations, basis functions);
- The C++ programming model (templates, object-oriented design);
- The linear algebra backend (solvers, preconditioners).

The first labs are deliberately kept simple because even setting up a finite element mesh, assembling the stiffness matrix, and applying boundary conditions requires some work.

 **Why is deal.II respected?** Despite the initial complexity, `deal.II` is **very mature and widely used in scientific computing**. Aerospace, automotive, and energy companies use FEM frameworks like `deal.II`, FEniCS, or proprietary codes to simulate physical systems. Research groups in Europe and the US use `deal.II` on HPC clusters for multi-physics and optimization problems.

- ParaView is an **open-source data analysis and visualization application**. It's designed to handle very large scientific datasets (from MBs to TBs). Our finite element codes produce numerical solutions (vectors of values at mesh nodes, or fields defined in VTK/VTU file formats). These are not human-friendly to interpret. ParaView lets us **load the mesh and solution** files produced by `deal.II`. We can then **plot solutions in 2D/3D**, extract values along a line or surface, animate time-dependent results, compute integrals, etc..
- `gmsh` is an **open-source mesh generator** (also with a built-in post-processor). It allows us to create computational grids for finite element methods. For simple domains (intervals, unit squares, unit cubes), `deal.II` can generate meshes internally. But for **non-trivial geometries** (like irregular domains, or those with boundary partitions), we need an external mesh generator.

In addition, profiling and debugging tools (e.g. `TimerOutput`, `gperftools`) are used to analyze and optimize performance.

## Computational Environment

While the course suggests using the MK module system, a more versatile approach is to work with either:

- a **native installation** of the required software stack (`deal.II`, ParaView, `gmsh`, etc.), or
- a **Docker container**, which ensures reproducibility and avoids configuration issues.

These alternatives are recommended for who prefer independence from the university's MK modules and allow seamless experimentation on personal or cloud-based machines.

### ✂ Environment Setup

Download version 9.5.0 of **deal.II** (which we are using for the course) from their website, following their guide. If we are using WSL or Ubuntu, we can download it more easily using the command:

```
1 sudo apt-get install libdeal.ii-dev
```

Download the **ParaView** visualization software from its original website:

If we're using Ubuntu, the easier command for the latest version is:

```
1 sudo apt install paraview
```

## 3 FEM for Poisson 1D

### 3.1 What is the Poisson Equation?

The **Poisson equation** is one of the most fundamental Partial Differential Equations (PDEs). In general form (in multiple dimensions):

$$-\Delta u(x) = f(x), \quad x \in \Omega \quad (19)$$

With some boundary conditions on  $\partial\Omega$ . Where:

- $u(x)$  is the **unknown function** (temperature, displacement, potential, etc.).
- $\Delta$  is the **Laplacian operator**, i.e. sum of second derivatives.

$$\Delta u = \frac{\partial^2 u}{\partial x_1^2} + \frac{\partial^2 u}{\partial x_2^2} + \cdots \quad (20)$$

- $f(x)$  is the **source term** (where heat is produced, where force acts, etc.).

So the Poisson equation says **the curvature of  $u$  (second derivate) balances the source  $f$** .

#### 🔍 What does “1D” mean?

Normally the Poisson equation is written in 2D or 3D (for surfaces and volumes).

- In **2D**, it's like heat distribution on a plate.
- In **3D**, it's like heat or potential in a cube.

In **1D**, the domain  $\Omega = (0, 1)$  is just a line (an interval). So the Laplacian reduces to an ordinary second derivative:

$$\Delta u(x) = \frac{d^2 u}{dx^2}$$

Therefore, in 1D, the Poisson equation looks like:

$$-u''(x) = f(x) \quad (21)$$

If we allow a variable coefficient  $\mu(x)$ , it becomes:

$$-(\mu(x)u'(x))' = f(x)$$

#### Example 1: Physical analogy

Imagine a **metal bar of length 1**. Fix both ends to zero temperature (they're in contact with ice). Apply a **heat source** (or sink, if negative) in some region of the bar. Then the **temperature distribution** inside the bar is described by the 1D Poisson equation.

Another analogy. Think of a **stretched elastic string** fixed at both ends. Apply a **vertical load** (the forcing  $f$ ) on some region. The resulting shape of the string  $u(x)$  satisfies the Poisson equation.

### The core idea

The Poisson equation links:

- The **curvature** of the unknown function  $u(x)$  (its second derivate)
- To the **source term**  $f(x)$ .

Formally:

$$-u''(x) = f(x) \quad (\text{in 1D})$$

That means wherever  $f(x)$  is nonzero, it *forces* the function  $u(x)$  to bend (curve). If  $f(x) = 0$ , the equation reduces to:

$$-u''(x) = 0 \quad \implies \quad u''(x) = 0$$

Whose solutions are straight lines. So **no sources, flat solution**.

### Physical interpretations

We can understand Poisson in multiple ways, depending on the field:

1. **Heat conduction.** The equation says: “The way temperature curves along the bar is dictated by how much heat we add/remove locally”.
  - $u(x)$ : temperature.
  - $f(x)$ : heat sources (positive) or sinks (negative).
2. **Electrostatics.** The equation says: “Charges create curvature in the potential”.
  - $u(x)$ : electric potential.
  - $f(x)$ : charge distribution (density).
3. **Elasticity.** The equation says: “Where we press on the string, it bends”.
  - $u(x)$ : displacement of a string or membrane.
  - $f(x)$ : applied load (force per unit length).

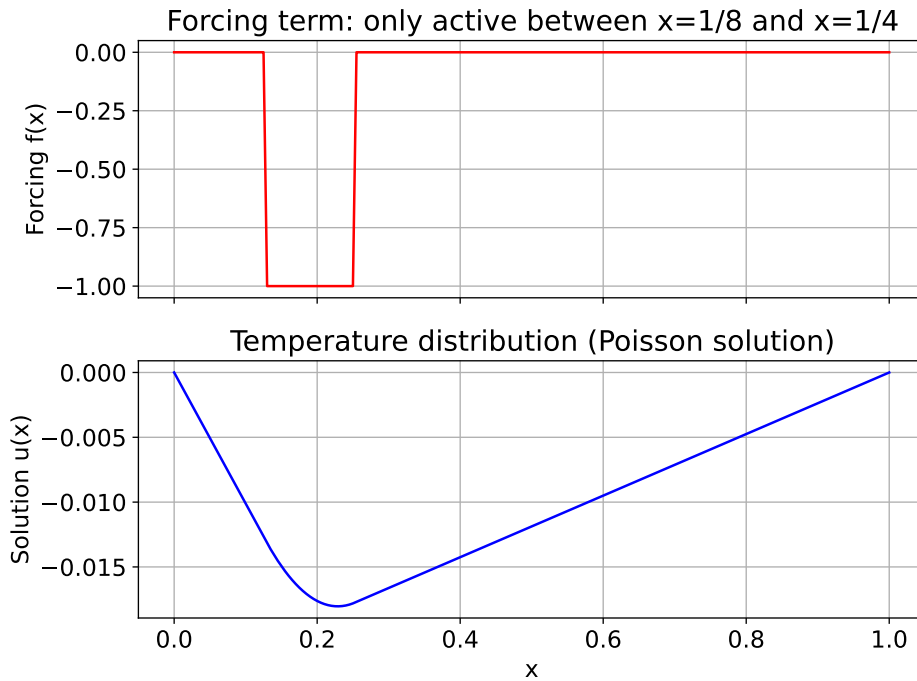

Figure 4: Visual explanation of the 1D Poisson problem. **Top graph (red)** is the forcing term  $f(x)$ . It is **zero everywhere**, except between  $x = \frac{1}{8}$  and  $x = \frac{1}{4}$ , where it is negative ( $-1$ ). That means only in that region we have a “sink” of heat. The **bottom graph (blue)** is the solution  $u(x)$ , i.e. the **temperature profile** along the bar. The ends are fixed at  $u(0) = u(1) = 0$ . In the middle, the solution bends downward because of the negative forcing. Outside the forcing region, the solution is almost straight (since  $f = 0$ , then the curvature is 0). So visually, the bar stays at 0 at the ends, but dips in the middle where we apply the negative forcing.

For example, this graph could represent heat conduction in a bar.

- $u(x)$ : **temperature** along a thin bar of length 1.
- Boundaries: both ends clamped to  $0^\circ\text{C}$  (in contact with ice).
- $f(x) = -1$  between  $x = \frac{1}{8}$  and  $x = \frac{1}{4}$ : this is like a **cooling region** (a heat sink).
- Physical picture: the bar stays cold at the ends and gets even colder in the middle where cooling is applied, producing the “dip”.

### ❓ What is the purpose of the Poisson equation?

The Poisson equation gives us the **response of the system**, not just the input. Why? Because physical systems are not isolated points:

- Temperature at a point depends on how heat flows along the entire bar.
- Displacement of a string at one point depends on forces applied nearby and the string's stiffness.
- Potential at a point depends on all surrounding charges.

The Poisson equation encodes that **interaction through curvature**:

$$-u''(x) = f(x)$$

- The second derivate  $u''$  measures how much the solution bends.
- The boundary conditions (ends fixed at 0) propagate constraints.
- The combination of  $f$  and boundaries gives the actual **shape of the solution**.

For example, consider figure 4 on page 26. In particular, consider our forcing (the red curve in the top graph). It is localized, but the solution (the blue curve in the bottom graph) is **spread out**:

- The dip is not only in the forcing region, it extends beyond, up to the ends.
- This spreading comes from the diffusion mechanism encoded by Poisson.

So if we only look at  $f(x)$ , we know *where the cause is*. But if we solve Poisson, we know *how the whole system reacts*.

#### Example 2: Real-world analogy

Imagine putting an ice cube (the sink) in one part of a metal bar. From the forcing alone, we know *where* the cooling happens. But we don't know how the **temperature profile along the whole bar** looks; is the bar uniformly cold? Does the dip propagate? Solving Poisson tells us exactly the **temperature distribution everywhere**, considering both the sink and the fixed-zero boundary conditions.
